In recent years, applications of ICs have been diversified and their performance has improved. For example, transistors have become smaller and ICs have become denser, so that the chips are mounted in a smaller area and at a higher density. The improvement of the performance of an IC leads to an increase of the amount of heat generated in an IC chip. The heat generated from an IC chip increases the temperature of the IC chip, resulting in that a temperature sensor attached to the IC chip detects a temperature change and outputs a temperature signal of an IC chip. Conventional technique related to temperature detection of an IC chip is disclosed in Japanese Unexamined Patent Publication No. 2007-230181. FIG. 5 is a block diagram illustrating a conventional temperature detection circuit. A temperature detection circuit 100 in FIG. 5 includes a temperature sensing circuit 101 and a controller 102. The temperature sensing circuit 101 includes an analog-to-digital converter (ADC) 1011, an amplifier 1012, a comparator 1013, a counter 1014, and a digital-to-analog converter (DAC) 1015. The analog-to-digital converter (ADC) 1011 receives an output of the amplifier 1012, converts the analog output to a digital signal and outputs the digital signal to the comparator 1013. The comparator 1013 compares a first reference voltage VREF1, which is constant, with the analog output and outputs a result of comparison as a digital value to
