All-new character development feature that lets you choose a character's appearance, equipment, and play style.

Vespa conoides Vespa conoides is a small vespoid wasp from the family Vespidae. It is native to the Palearctic, and has become an invasive species in North America. There it has changed its name, and became its own species, Vespula conoides. It is now known to parasitise honey bees. Like most other wasps the females are winged. Adult females are about 4–8 mm in length, and are yellow and black in colour. This species of wasp flies in summer and autumn, and the larger males sometimes form big aggregations. In the Eastern parts of the Nearctic Region hibernation takes place during the winter months. The larvae live in the ground. Unlike most wasps in the Vespa genus, this species does not bite or sting. This wasp can be host to chytridiomycosis; however this has not been scientifically confirmed. The disease is known to affect mostly amphibian, reptile, and bird species. As when the disease is present, most of the infected individuals wither and die and their body fluids become infected with specific fungus chytrid. The American Vespa conoides have been established to have developed chytridiomycosis. The pesticide Sevin is known to kill the disease, but costs should be considered. Studies also show that the European Vespa conoides does not acquire chytridiomycosis. The composition of the nest found of the European Vespa conoides resembles that of the American species; however, the American one's nests have a smaller number of females. When mounting an attack, the vespa is said to vibrate, or "drum", the host. This begins as a faint vibration on the ground, but becomes more pronounced and audible. The host reacts with increased movement, and the stinging. The host may go limp in this time. During this attack the animal is highly mobile, and may sting individuals near and far. Vespa

strands) of a particular repeat length, as does most of the genome of *Bacillus subtilis*. In most of the *B. subtilis* genome these regions are located in a tandem repeat array. For example, long tandemly repeated sequences in the *B. subtilis* genome tend to form palindromic hairpin structures. They are called palindromic regions, and their palindromic sequences are called palindromes. The palindromic regions tend to be enriched for transposable element sequences, and they may be involved in the horizontal transmission of transposons. Some transposons such as prophage elements are integrated into the same end of the palindromes. The regions are duplicated by homologous recombination and direct repeat transposition. There are, for example, approximately 30 palindromes of approximately 200 bp repeated at the terminus of the *B. subtilis* chromosome. The palindromic regions have a near-identical sequence in the forward and reverse orientation at the end of the palindromes, and this could allow reciprocal recombination. As the *B. subtilis* genome is circular, these palindromic regions could recombine with palindromes located on the opposite end. By this process, the *B. subtilis* genome becomes a chromosome.
